General Trees & Binary Trees

CSC212: Data Structures

Trees

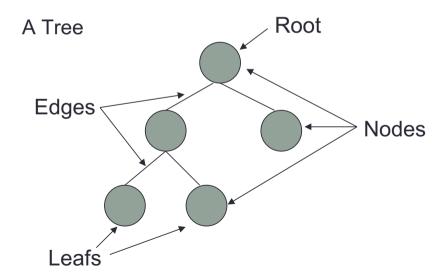

- Previous data structures (e.g. lists, stacks, queues) have a linear structure.
- Linear structures represent one-to-one relation between data elements.
- Trees have a nested or a hierarchical structure.
- Hierarchical structures represent one-to-many relation between data elements.

Trees

- Examples of situations were one-to-many relations exist... these can be represented as trees.
 - Relation between a parent and his children.
 - Relation between a person and books he owns.
 - Relation between a football team and the players on the team.
 - Card catalog in a library.

Trees: Some Terminology

• A tree is represented as a set of <u>nodes</u> connected by <u>edges</u>.

Trees: Comparison with Lists

A List

- ▶ Unique <u>first</u> element.
- ► Unique <u>last</u> element.
- ► Each element, other than the first and the last, has a unique predecessor and a unique successor.

A Tree

- Unique first node called root.
- Each node has successors, called its children.
- Each node has one predecessor, called parent.
- <u>Leafs</u> have no children.
- ▶ Root has no parent.

Trees: More Terminology

- Simple path: a sequence of distinct nodes in the tree.
- Path length: number of nodes in a path.
- Siblings: two nodes that have the same parent.
- <u>Ancestors</u>: given a node A in a tree, the parent of the node A and the ancestors of the parent of A , are ancestors of A.

Trees: More Terminology

Parent: a parent of a node is its predecessor.

Child: a child of a node is its successor.

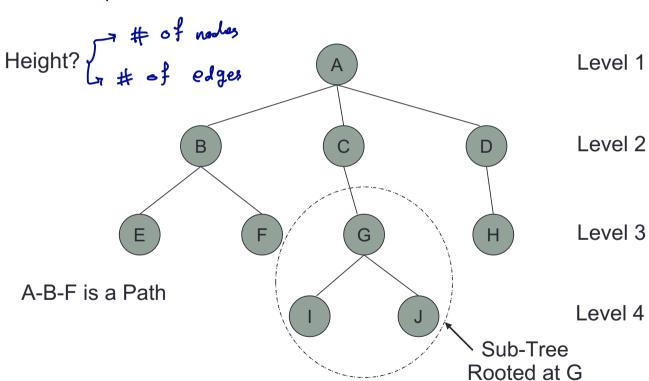

Root: a unique node without any predecessor.

Leafs: nodes without any children.

<u>Descendents</u>: given a node A in a tree, the children of A and all descendents of the children of A are descendents of A.

Trees: More Terminology

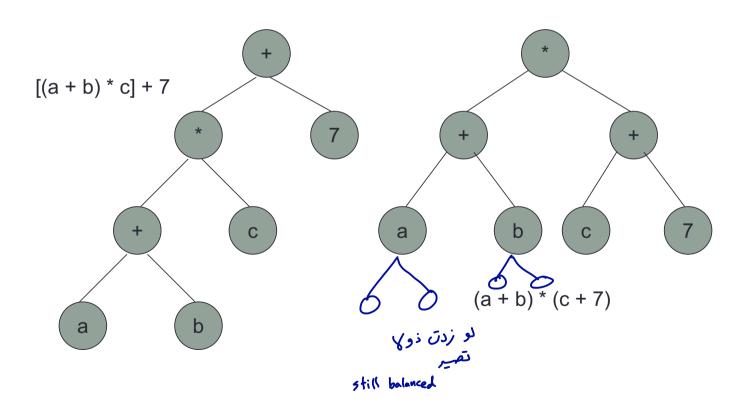

two different schools:

Binary Trees

- A binary tree is a tree with the following:
 - 1. Each node can have at most two subtrees and therefore at most two children.
 - 2. Each subtree is identified as being either the left subtree or the right subtree of the parent.
 - 3. It may be empty.
- Nodes in a binary tree may be composite e.g. of variable type 'Type'.

Binary Trees

Elements: The elements are nodes, each node contains the following data type: Type and has LeftChild and RightChild references.

Structure: hierarchical structure; each node can have two children: left or right child; there is a root node and a current node.

<u>Domain:</u> the number of nodes in a binary tree is bounded; domain contains empty tree, trees with one element, two elements, ...

Operations:

1. Method Traverse (Order ord)

requires: Binary Tree (BT) is not empty.

input: ord. Order

results: Each element in the tree is processed exactly once by a user supplied procedure. The order in which nodes are processed depends on the value of ord (Order = {preorder, postorder, inorder})

preorder: each node processed before any node in either of its subtrees. Parent - Left child - right child

inorder: each node is processed after all its nodes in its left subtree and before any node in its right subtree. Left child a forest a right child

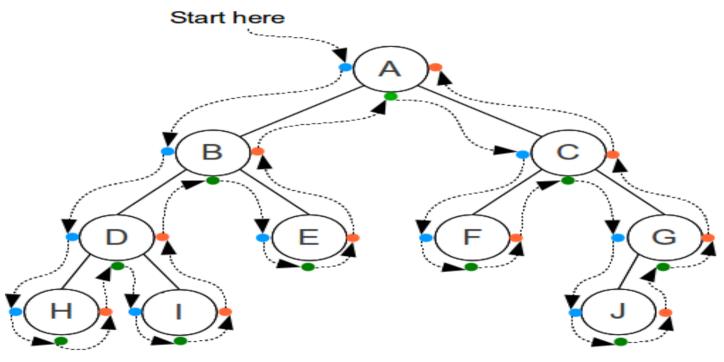

postorder: each node is processed after all its nodes in both of its subtrees. Leftchild - right child - Parent

output: none.

Tree Traversals

- To traverse a tree means to process (e.g. printing it) each element in the tree.
- Tree traversals
 - n! ways of traversing a tree of n nodes.
 - pre-order, in-order, post-order ? three natural traversals orders.
- List traversals
 - n! ways of traversing a list of n nodes.
 - front-to-back, or back-to-front. ? two natural traversals orders.

Tree Traversals Example

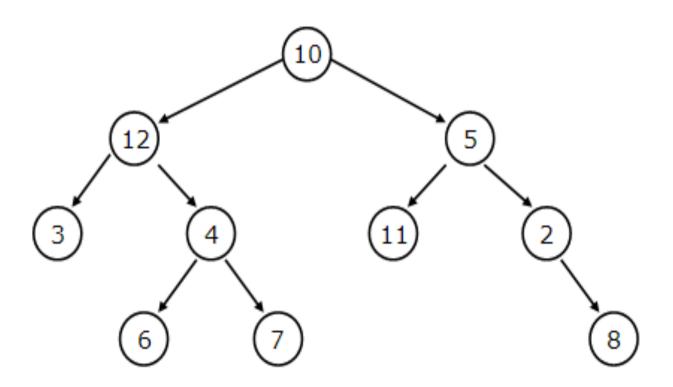

Pre-Order In-Order Post-Order

https://en.wikipedia.org/wiki/Tree traversal

Tree Traversals Example

Operations:

2. Method Insert (Type e, Relative rel, boolean inserted)

```
(Relative = {leftchild, rightchild, root, parent})
```

requires: (1) Full () is false and (2) either (a) rel = root and Empty() is true or (b) rel <> root and rel <> parent and Empty() is false.

input: e, rel.

results: if case (1) rel = leftChild, current node has a left child, or (2) rel = rightChild, current node has a right child, then inserted is false. Else a node containing e is added as rel of the current node in the tree and becomes the current node and inserted is true.

output: inserted.

3. Procedure DeleteSub ()

requires: Binary tree is not empty.

input: none

results: The subtree whose root node was the current node is deleted from the tree. If the resulting tree is not empty, then the root node is the current node.

output: none.

4. Procedure Update (Type e).

requires: Binary tree is not empty.

input: e.

results: the element in e is copied into the current node.

output: none.

5. Procedure Retrieve (Type e)

requires: Binary tree is not empty.

input: none

results: element in the current node is copied into e.

output: e.

Procedure Find (Relative rel, boolean found) requires: Binary tree is not empty. input: rel. results: The current node of the tree is determined by the value of rel and previous current node... output: found. 7. Procedure Empty (boolean empty). requires: None. input: none results: If Binary tree is empty then empty is true; otherwise empty is false. output: empty.

8. Procedure Full (boolean full)
 requires: None.
 input: None.
 results: if the binary tree is full then full is true

otherwise false.

output: full.

ADT Binary Tree: Element

```
public class BTNode <T> {
         public T data;
         public BTNode<T> left, right;
         /** Creates a new instance of BTNode */
         public BTNode(T val) {
                   data = val;
                   left = right = null;
         public BTNode(T val, BTNode<T> I, BTNode<T> r){
                   data = val;
                   left = I;
                   right = r;
```

ADT Binary Tree: Order & Relative Classes

- These definitions are in separate files and define:
 - The Order class.

```
public enum Order {preOrder, inOrder, postOrder};
```

The Relative class.

public enum Relative {Root, Parent, LeftChild, RightChild};

```
public class BT<T> {
        BTNode<T> root, current:
        /** Creates a new instance of BT */
        public BT() {
                root = current = null;
        public boolean empty(){
                return root == null;
```

```
public class BT<T> {
        BTNode<T> root, current:
        /** Creates a new instance of BT */
        public BT() {
                root = current = null;
        public boolean empty(){
                return root == null;
```

```
RC
public class BT<T> {
        BTNode<T> root, current:
                                                       null
                                                      true
        /** Creates a new instance of BT */
        public BT() {
                root = current = null;
        public boolean empty(){
                return root == null;
                                                      false
```

```
public T retrieve() {
          return current.data;
}

public void update(T val) {
          current.data = val;
}
```

```
public T retrieve() {
         return current.data;
public void update(T val) {
         current.data = val;
```

```
public T retrieve() {
         return current.data;
public void update(T val) {
         current.data = val;
```

```
