QUEUE

CSC212:Data Structure

Queue

- Queue: First In First Out (FIFO).
 - Used in operating systems, simulations etc.
- Priority Queues: Highest priority item is served first.
 - Used in operating systems, printer servers etc.

ADT Queue: Specification

Elements: The elements are of generic type < Type> (The elements are placed in nodes for linked list implementations).

Structure: the elements are linearly arranged, and ordered according to the order of arrival. Most recently arrived element is called the back or tail, and least recently arrived element is called the front or head.

Domain: the number of elements in the queue is bounded therefore the domain is finite. Type of elements: Queue

ADT Queue: Specification

Operations:

interface

Method Enqueue (Type e)

requires: Queue Q is not full. input: Type e.

results: Element e is added to the queue at its tail. output:

none.

Method Serve (Type e)

requires: Queue Q is not empty. input: none

results: the element at the head of Q is removed and its value

assigned to e. output: Type e.

3. Method Length (int length)

requires: none. input: none

results: The number of element in the Queue Q is returned.

output: length.

ADT Queue: Specification

Operations:

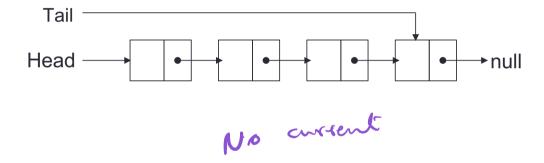

Method Full (boolean flag).

requires: none. input: none

results: If Q is full then flag is set to true, otherwise flag is set

to false. output: flag.

ADT Queue (Linked-List)

ADT Queue (Linked-List): Element

```
public class Node<T> {
        public T data;
        public Node<T> next;
        public Node() {
                data = null:
                next = null;
        public Node(T val) {
                data = val;
                next = null;
       // Setters/Getters?
```

Node is the sand

ADT Queue (Linked-List): Representation

```
public class LinkedQueue<T> {
    private Node<T> head, tail;
    private int size;

/** Creates a new instance of LinkedQueue */
    public LinkedQueue() {
        head = tail = null;
        size = 0;
    }
```

ADT Queue (Linked-List): Representation

```
Size = 0
public class LinkedQueue<T> {
                                                         HT
        private Node<T> head, tail;
        private int size;
                                                         null
        /** Creates a new instance of LinkedQueue */
        public LinkedQueue() {
                head = tail = null;
                size = 0:
```

```
public boolean full() {
        return false;
}

public int length (){
        return size;
}
```

```
public void enqueue(T e) {
                                                               Best casp
                  if(tail == null){
     why not
                          head = tail = new Node<T>(e);
      head?
Becouse it's FIFO
                  else {
                          tail.next = new Node<T>(e);
                          tail = tail.next;
                  size++;
```

```
public void enqueue(T e) {
        if(tail == null){
                head = tail = new Node<T>(e);
        else {
                tail.next = new Node<T>(e);
                tail = tail.next;
                            Example #1
            Size = 0
        size++HT
               null
```

```

```

```
public T serve() {
        T x = head.data;
        head = head.next;
        size--;
        if(size == 0)
                 tail = null;
                             Example #3
        returaize = 0
                                             H T
                                             null
```

- A fixed size array is used to store the data elements.
- As data elements are enqueued & served the queue crawls through the array from low to high index values.
- As the queue crawls forward, it also expands and contracts.

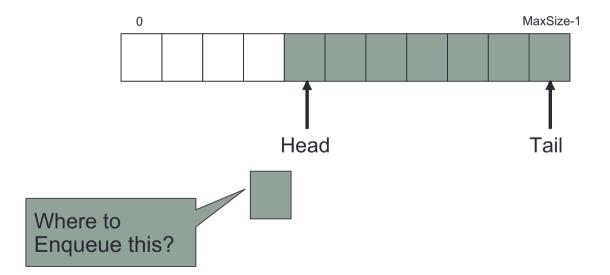

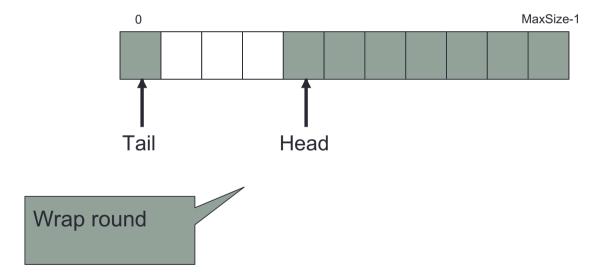

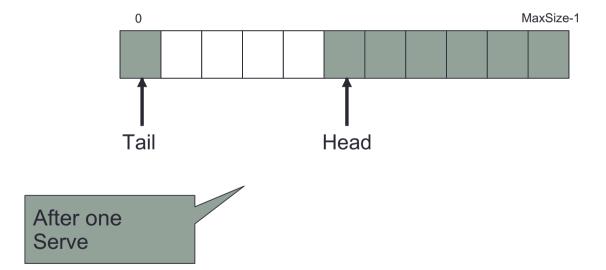

After one Serve

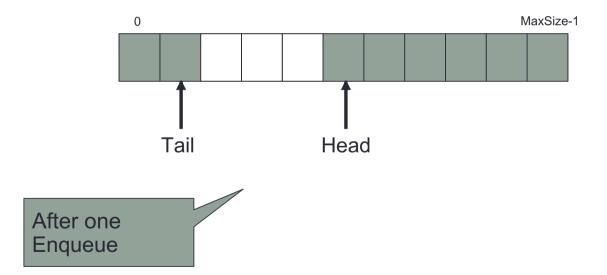

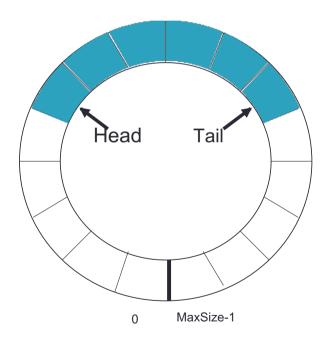

After one Enqueue

ADT Queue (Array): Representation

```
public class ArrayQueue<T> {
        private int maxsize;
        private int size;
        private int head, tail;
        private T[] data;
        /** Creates a new instance of ArrayQueue */
        public ArrayQueue(int n) {
                maxsize = n:
                size = 0:
                head = tail = 0;
                data = (T[])new Object[n];
```

ADT Queue (Array): Representation

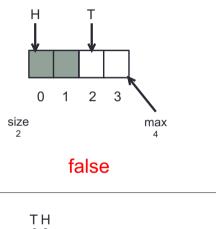

```
public class ArrayQueue<T> {
        private int maxsize;
        private int size;
        private int head, tail;
        private T[] data;

    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {

T e = data[head];

head = (head + 1) % maxsize;

size--;

return e;

}

Example #3

(0 + 1) % 4 = 1 % 4 = 1

T e = data[head];

o 1 2 3

max

size

1
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

```
public T serve () {
    T e = data[head];
    head = (head + 1) % maxsize;
    size--;
    return e;
}
```

Priority Queue

- Each data element has a priority associated with it. Highest priority item is served first.
- Real World Priority Queues: hospital emergency rooms (most sick patients treated first), events in a computer system, etc.
- Priority Queue can be viewed as:
 - View 1: Priority queue as an ordered list.
 - View 2: Priority queue as a set.

Elements: The elements are of type PQNode. Each node has in it a data element of generic type <Type> and a priority of type Priority (which could be int type).

Structure: the elements are linearly arranged, and may be ordered according to a priority value, highest priority element is called the <u>front</u> or <u>head</u> and least priority element is the back or <u>tail</u>.

Domain: the number of nodes in the queue is bounded therefore the domain is finite. Type of elements: PriorityQueue

Operations:

- 1. Method Enqueue (Type e, Priority p)
 - requires: PQ is not full. input: e, p.
 - results: Element e is added to the queue according to its priority. output: none.
- Method Serve (PQElement<Type> pqe)
 - requires: PQ is not empty. input: None
 - results: the element and the priority at the head of PQ is removed and returned. output: pge.
- Method Length (int_length)
 - input: results: The number of element in the PQ is returned. output: length.

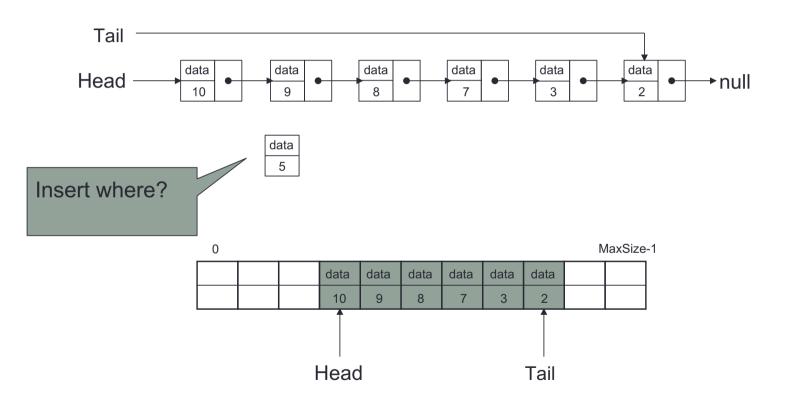

Operations:

Method Full (boolean flag).

requires: input:

results: If PQ is full then flag is set to true, otherwise

flag is set to false. output: flag.

ADT Priority Queue (Linked-List): Element

```
public class PQNode<T> {
         public T data;
         public Priority priority;
         public PQNode<T> next;
         public PQNode() {
                  next = null;
         public PQNode(T e, Priority p) {
                  data = e;
                  priority = p;
        // Setters/Getters?
```

ADT Priority Queue (Linked-List): Element (int Priority)

```
public class PQNode<T> {
         public T data;
         public int priority;
         public PQNode<T> next;
         public PQNode() {
                  next = null;
         public PQNode(T e, int p) {
                  data = e;
                  priority = p;
        // Setters/Getters?
```

ADT Priority Queue (Linked-List): Representation

```
public class LinkedPQ<T> {

public PQElement<T> serve(){
        PQNode<T> node = head:
        PQElement<T> pqe=new PQElement<T>(node.data,node.p);
Example #3
        head = head.next;
        size--;
        return pge;
```

ADT Priority Queue

- Implementations
 - Linked List: Enqueue is O(n), Serve is O(1).
 - Array Implementation: Enqueue is O(n), Serve is O(1).
 - Heap: Enqueue is O(log n), Serve is O(log n) ? Heaps to be discussed later.

- Double ended queue (or a deque) supports insertion and deletion at both the front and the tail of the queue.
- Supports operations: addFirst(), addLast(), removeFirst() and removeLast().
- Can be used in place of a queue or a stack.

Operations: (Assume all operations are performed on deque DQ)

Method addFirst (Type e)

requires: DQ is not full. input: e.

results: Element e is added to DQ as first element. output:

Method addLast (Type e)

requires: DQ is not full. input: e

results: Element e is added to DQ as last element. output:

Method removeFirst (Type e)

requires: DQ is not empty. input: none results: Removes and returns the first element of DQ. output: e.

```
Method removeLast (Type e)
        requires: DQ is not empty. input: none.
        results: Removes and returns the last element of DQ. output:
     e.
     Method getFirst (Type e)
        requires: DQ is not empty. input: none
        results: Returns the first element of DQ. output: e.
6.
     Method getLast (Type e)
        requires: DQ is not empty. input: none
        results: Returns the last element of DQ. output: e
     Method size (int x)
        input: none results: Returns the number of elements in DQ.
     output: x
```

8. Method isEmpty (boolean x) input: none results: if DQ is empty returns x as true otherwise false. output: x

Complexity so far?

Operation	Queue (LL)	Queue (A)	Priority Queue (LL)	Priority Queue (CA)
Full	0(1)	0(1)	0(1)	ω_{1}
Length	0(1)	0(1)	$\alpha(1)$	o(\)

Static Method Enquiry (LinkedQueue/ArrayQueue)

```
user method
```

Member Method Enquiry (LinkedQueue)

```
Implementer method public T enquiry() {
    return head.data;
}
```

Member Method Enquiry (ArrayQueue)

```
public T enquiry() {
     return data[head];
}
```

ToDo

- Read 5.2, 5.3 of the Textbook.
- Add "int length()" method in the LinkedQueue class with O(n) complexity.
- Add "int length(ArrayQueue<T> q)" in the Test class of ArrayQueue. The Queue must remain unchanged after the operation.
- Add "T enquiry(ArrayQueue<T> q)" in the Test class of ArrayQueue. It should return the data of the head without changing the queue at the end of the call.
- Implement DQueue (Double-ended queue) using a Java class using Linked-List.
- Test this DQueue using a test Class.
